Well, individual bison align their movements more strongly with related conspecifics! So that is cool, but it opens a new door to many other ideas... does this pattern scale to how bison spend time with other bison over time (strength of connections in the broader network) or where an individual lies within the network of connections (centrality) over time? Does age modulate this connection? I've got to do some thinking of what could be interesting here. If you have any initial thoughts, please let me know!
